Computational Models #1

Handout Mode

Nachum Dershowitz & Yishay Mansour

March 13-15, 2017

Lecture Outline

- Motivation
- Languages, words and alphabets
- Finite automata and regular languages
- Regular operations

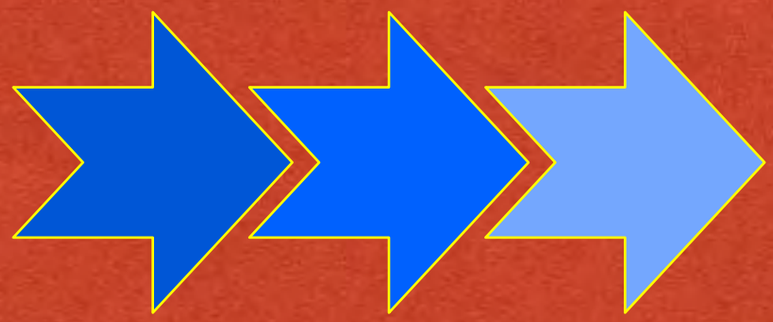
- Sipser, Chapter 1

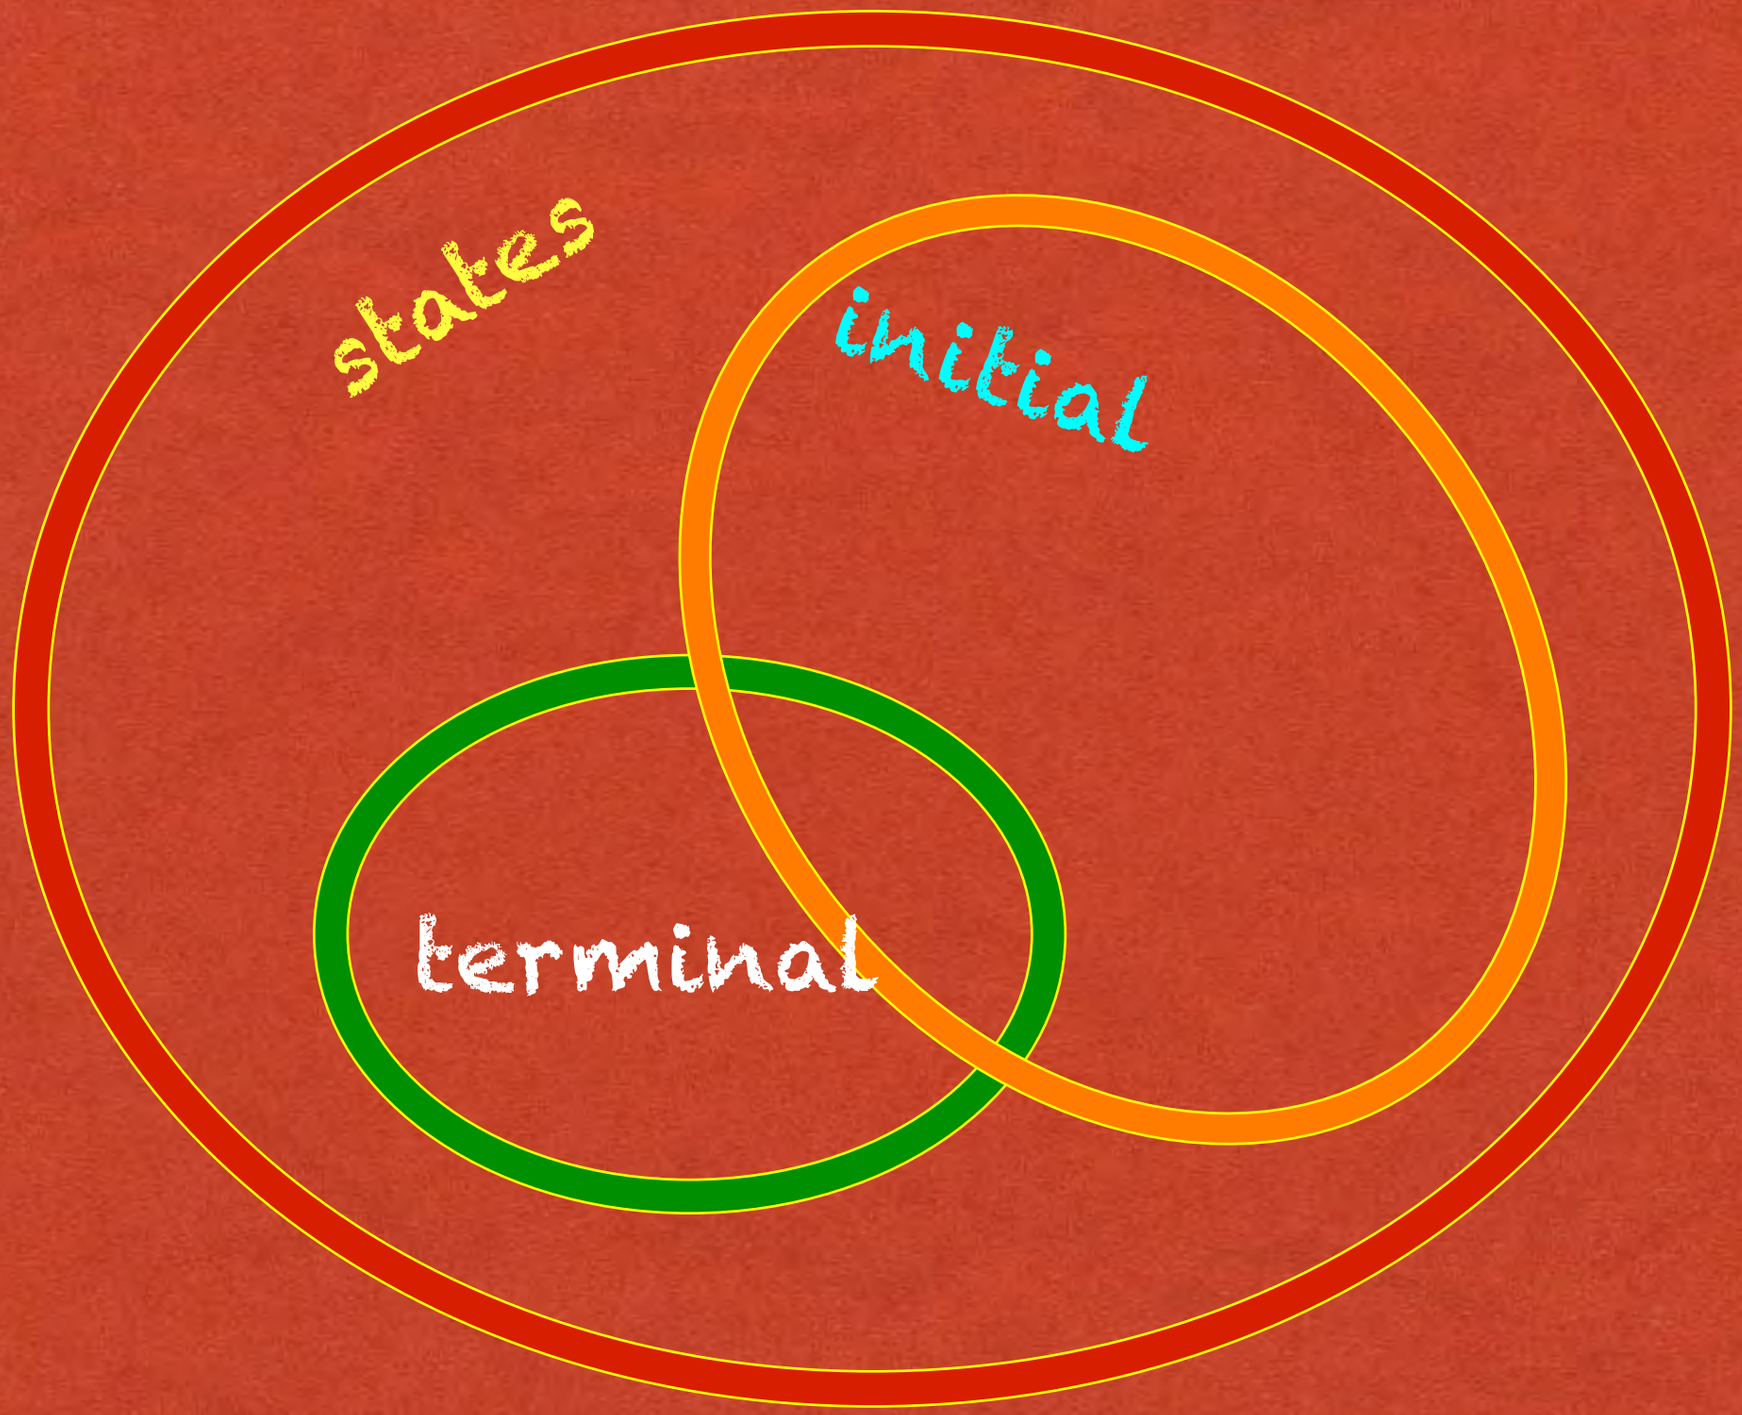
Time Magazine

- Put the right kind of software into a computer, and it will do whatever *you* want it to. There may be limits on what *you* can do with the machines themselves, but there are no limits on what *you* can do with software.

Chess

- Games: $10^{10^{50}}$
- Positions: 10^{40}
- Positions: 20, 400, 5362, 71852,
  809896(?), 9132484(?), ...





states
initial
terminal

Part I

Languages, words and alphabets

Languages, words and alphabets

Definition 1

An alphabet Σ is a finite set of letters.

- $\Sigma = \{a, b, c, \ldots, z\}$ – the English alphabet.
- $\Sigma = \{\alpha, \beta, \gamma, \ldots, \zeta\}$ – the Greek alphabet.
- $\Sigma = \{0, 1\}$ – the binary alphabet.
- $\Sigma = \{0, 1, \ldots, 9\}$ – the digital alphabet.

Definition 2

A word (i.e., string) over Σ, is a finite sequence of letters from Σ.

The collection of all strings over Σ is denoted by Σ^*.

For $\{0, 1\}$, the binary alphabet, ε, 1, 0, 000000000, 1111111000 are all members of Σ^*.

Definition 3

A language over Σ is a (possibly infinite) subset of Σ^*.

Language Examples

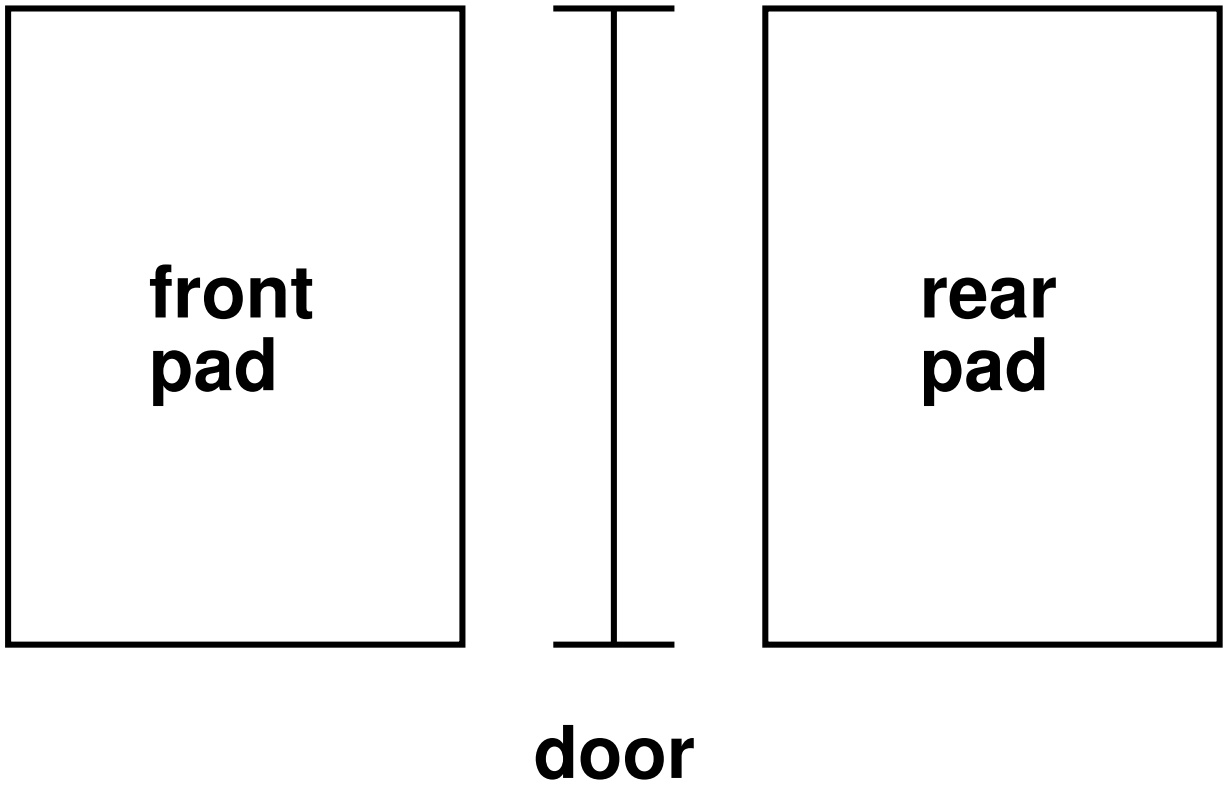
- Modern English.
- Ancient Greek.
- All prime numbers, written using digits.
- $\mathcal{A} = \{w \in \{0,1\}^* : w \text{ has at most seventeen } 0\text{'s}\}$.
- $\mathcal{B} = \{0^n 1^n : n \geq 0\}$.
- $\mathcal{C} = \{w \in \{0,1\}^* : w \text{ has an equal number of } 0\text{'s and } 1\text{'s}\}$.

Make sure you understand what the above notions stand for...

Part II

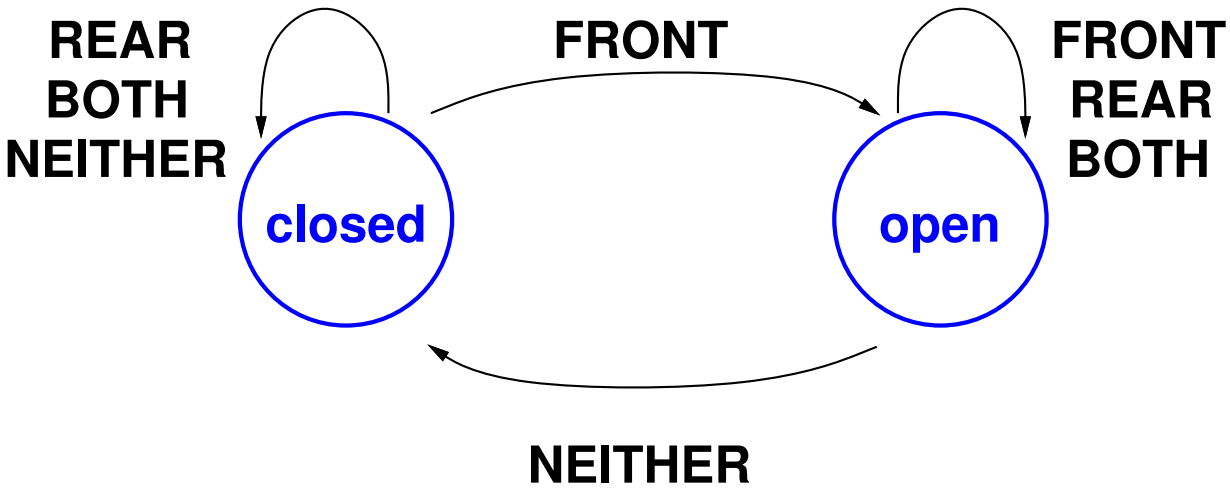
Finite Automata

Example: A One-Way Automatic Door



- open when person approaches
- hold open until person clears
- don’t open when someone standing behind door

The Automatic Door as DFA



- States:
  - OPEN
  - CLOSED
- Sensor:
  - FRONT: someone on front pad
  - REAR: someone on rear pad
  - BOTH: someone(s) on both pads
  - NEITHER no one on either pad.

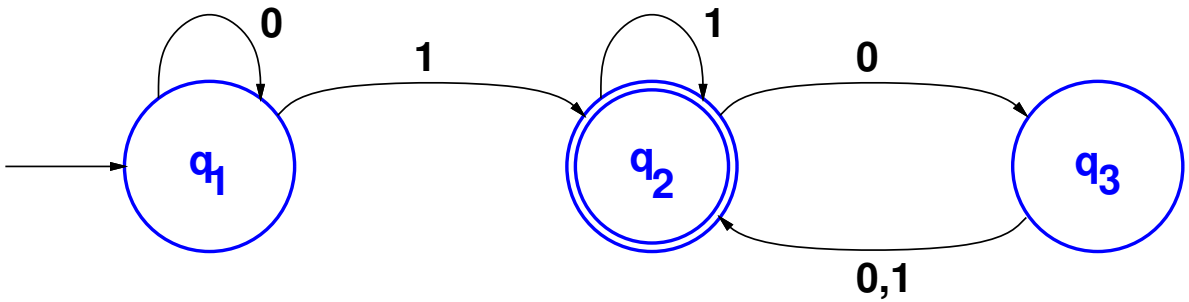
The Automatic Door as DFA

A DFA is Deterministic Finite Automata

	neither	front	rear	both
closed	closed	open	closed	closed
open	closed	open	open	open

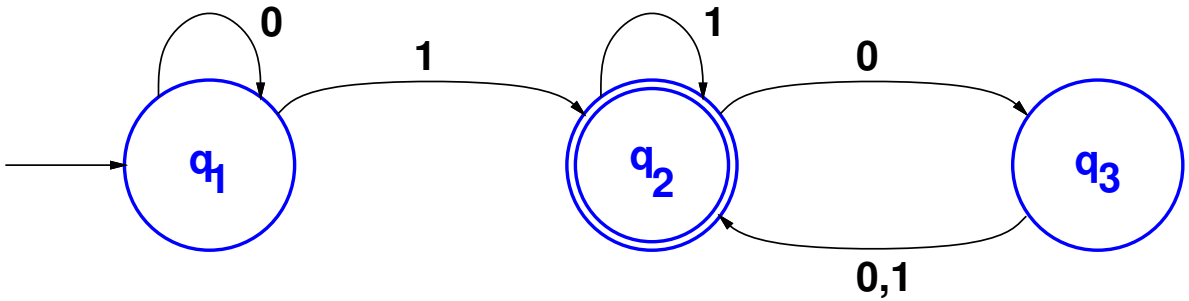
DFA: Informal definition

The machine M_1:



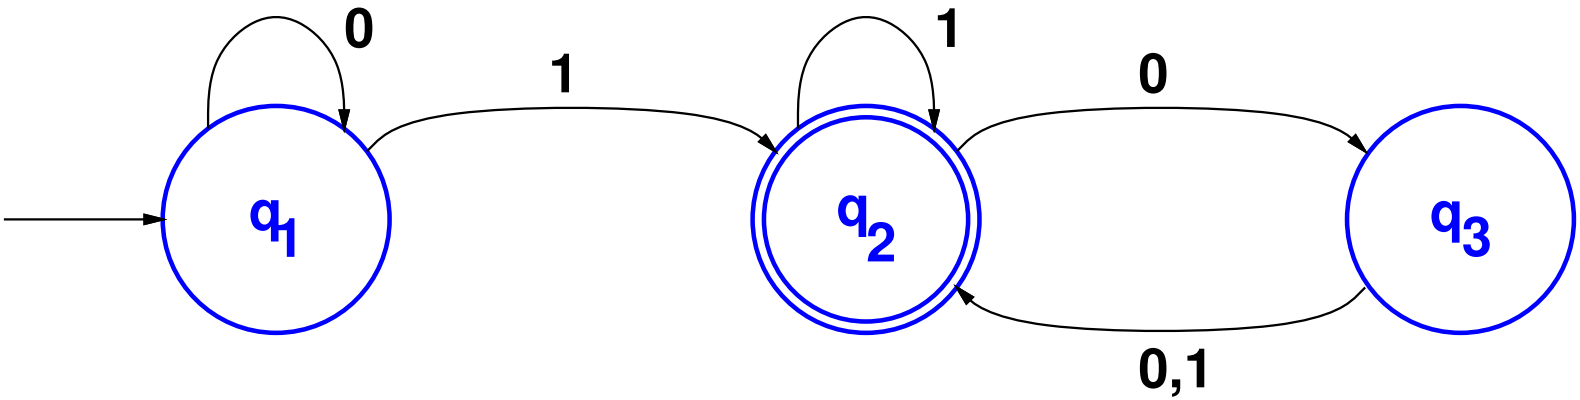
- States: q_1, q_2, and q_3.
- Start state: q_1 (arrow from "outside").
- Accept state: q_2 (double circle).
- State transitions: arrows tagged with letters.

DFA: Informal definition (cont.)



- On an input string
  - DFA begins in start state q_1
  - after reading each symbol, DFA makes state transition with matching label.
- After reading last symbol, DFA “produces" output:
  - accept if DFA is an accepting state.
  - reject otherwise.

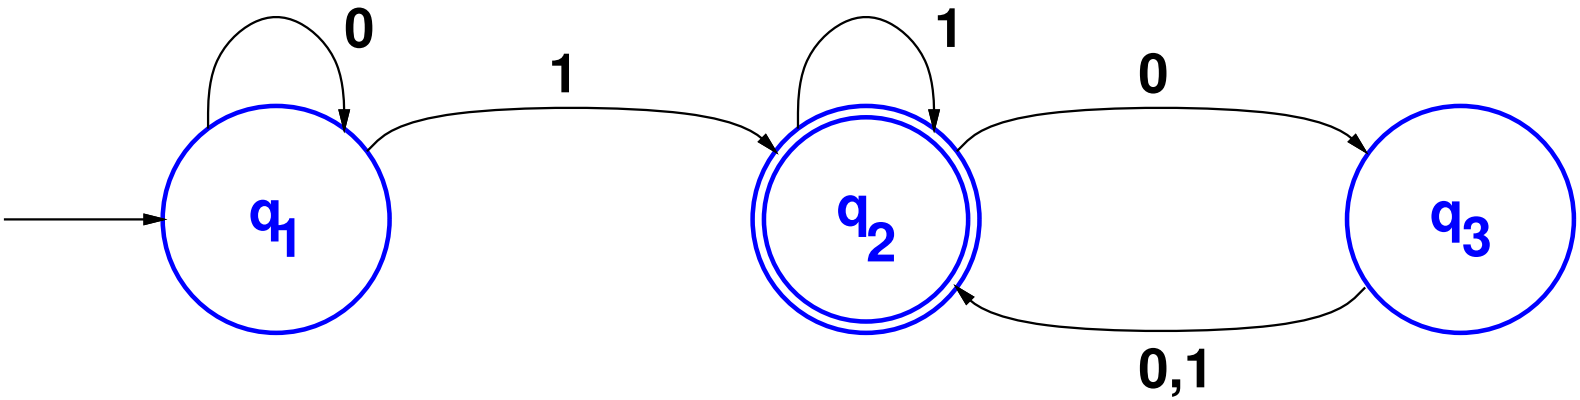
DFA: Informal definition (cont..)



What happens on the following input strings:

- 1101
- 0010
- 01100
- In general?!

DFA: Informal definition (cont...)



This DFA accepts

- All input strings that end with a 1
- All input strings that contain at least one 1, and end with an even number of 0's
- No other strings

Proof: ?

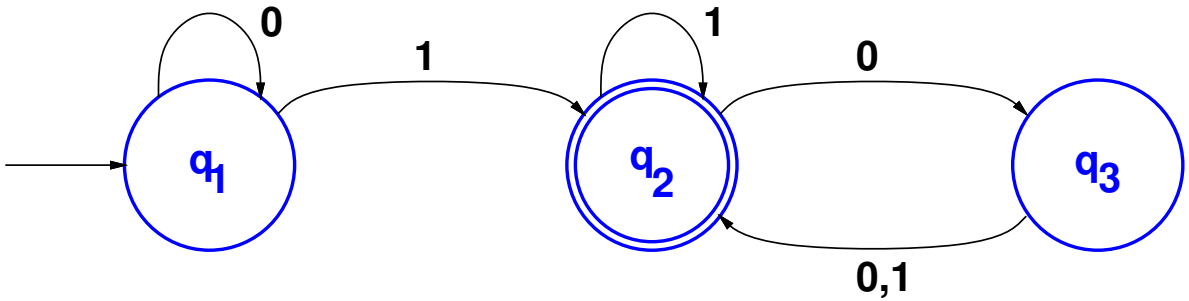
DFA - Formal Definition

Definition 4

A deterministic finite automaton (DFA) is a 5-tuple $(Q, \Sigma, \delta, q_0, F)$, where

- Q is a finite set called the states
- Σ is a finite set called the alphabet
- $\delta : Q \times \Sigma \to Q$ is the transition function
- $q_0 \in Q$ is the start state
- $F \subseteq Q$ is the set of accept states

Back to M_1



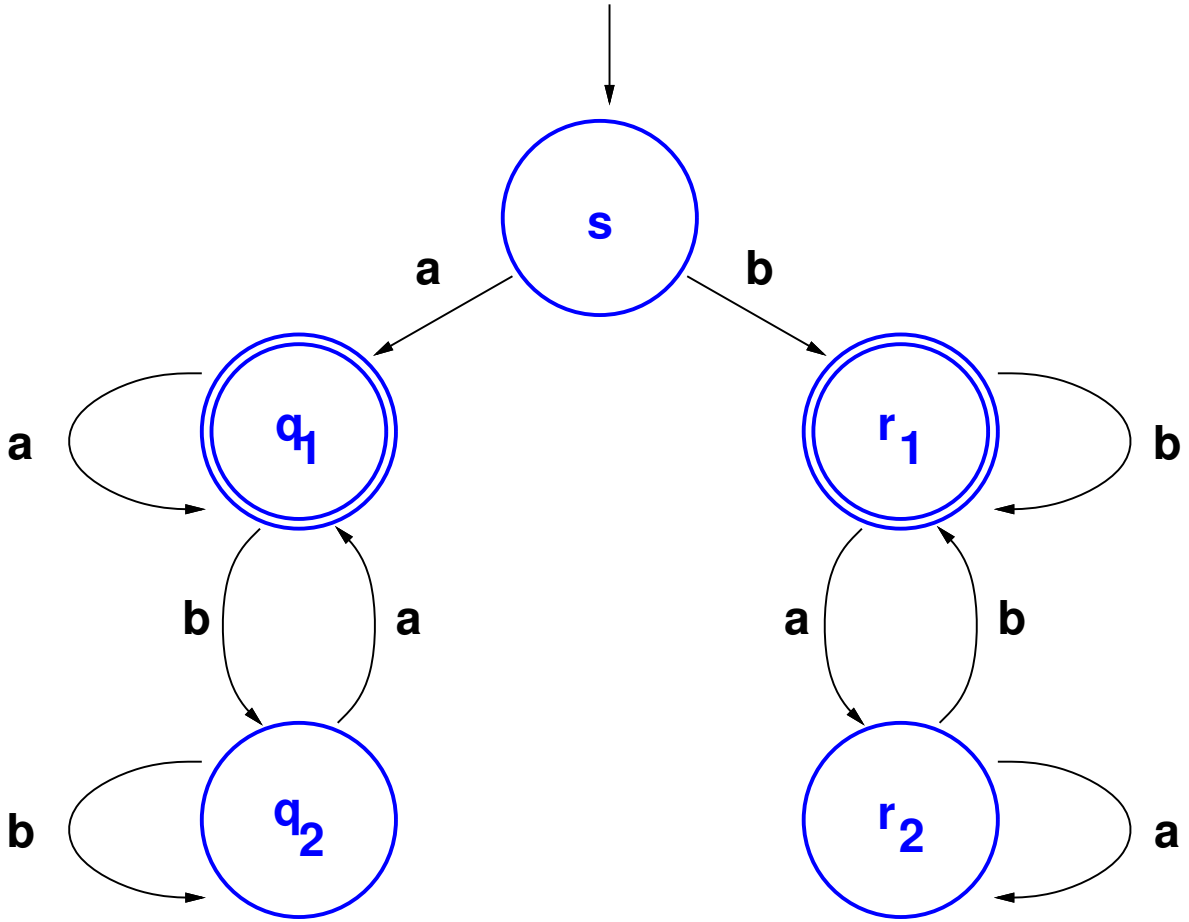
$M_1 = (Q, \Sigma, \delta, q_1, F)$ where

- $Q = \{q_1, q_2, q_3\}$, $\Sigma = \{0, 1\}$,
- the transition function δ is

	0	1
q_1	q_1	q_2
q_2	q_3	q_2
q_3	q_2	q_2

- q_1 is the start state
- $F = \{q_2\}$.

Another Example



Formal Model of Computation

Definition 5

$M = (Q, \Sigma, \delta, q_0, F)$ accepts $w \in \Sigma^*$ if $\widehat{\delta}_M(q_0, w) \in F$.

Definition 6 ($\widehat{\delta}$)

$\widehat{\delta}_M \colon Q \times \Sigma^* \mapsto Q$ is defined by

$$\widehat{\delta}_M(q, w) = \begin{cases} \delta(\widehat{\delta}(q, w_{1,\ldots,n-1}), w_n), & n = |w| \geq 1 \\ q, & w = \varepsilon. \end{cases}.$$

- $w_{1,\ldots,k}$ stands for the word $w_1, \ldots, w_k$ — the k-letter prefix of w ($w_{1,\ldots,0} = w_\emptyset = \varepsilon$)
- Note that $\widehat{\delta}_M(q, \sigma) = \delta(q, \sigma)$ for $\sigma \in \Sigma$.
- We write $\widehat{\delta}$ when M is clear from the context.

An equivalent definition

Definition 7 (Equivalent definition)

$M = (Q, \Sigma, \delta, q_0, F)$ accepts $w = w_1 w_2 \dots w_n$, if $\exists r_0, \dots, r_n \in Q$ s.t.,

- $r_0 = q_0$.
- $\delta(r_i, w_{i+1}) = r_{i+1}$, for all $0 \leq i < n$.
- $r_n \in F$.

The language of a DFA

Definition 8

$\mathcal{L}(M)$, the language of a DFA M, is the set of strings that M accepts.

We sometime say that M accepts the language $\mathcal{L}(M)$.

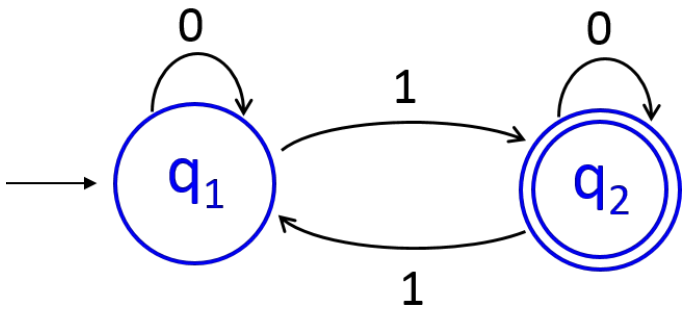
- M may accept many strings
- M accepts only one language.

What language does M accept if it accepts no strings?

Definition 9

A language is called regular, if some deterministic finite automaton accepts it.

Example: DFA M_2



- $Q = \{q_1, q_2\}$, $\Sigma = \{0, 1\}$, $F = \{q_2\}$, $\delta = ?$
- What is $\mathcal{L}(M_2) := \{w \in \{0,1\}^* : \widehat{\delta}(q_1, w) = q_2\}$?

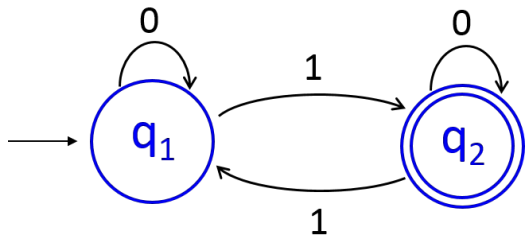
Theorem 10

$\mathcal{L}(M_2) = \{w \in \{0,1\}^* : \#_1(w)$ *is odd*$\}$. $\#_1(w)$ — *number of ones in* w.

- Proof by induction on the word length
- What does it mean?

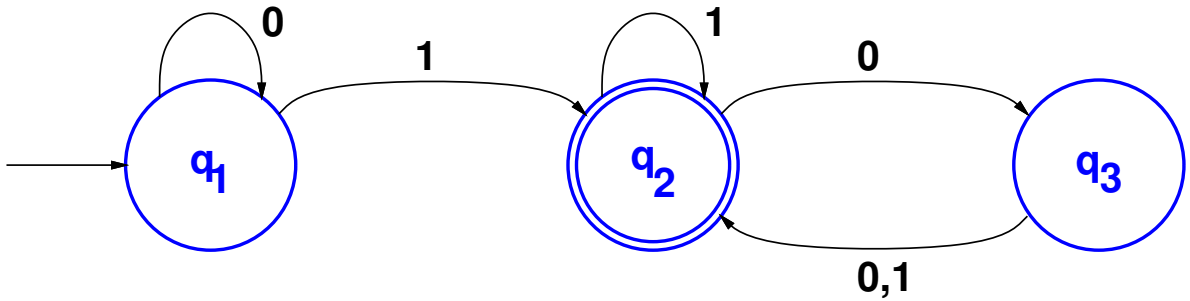
  The j'th assumption: $w \in \{0,1\}^j$ is in $\mathcal{L}(M)$ iff $\#_1(w)$ is odd

Proving $\mathcal{L}(M_2) = \mathcal{L}' := \{w \in \Sigma^* : \#_1(w)$ is odd$\}$



- *Basis (length 0):* $\varepsilon \notin \mathcal{L}'$ and $\widehat{\delta}(q_1, \epsilon) = q_1 \implies \epsilon \notin \mathcal{L}(M_2)$.
- *Step:* assume hypothesis holds for words of length $j \geq 0$.
- Let $x = y\sigma \in \{0,1\}^{j+1}$ for $\sigma \in \{0,1\}$ (hence, $|y| = j$).
- If $\#_1(y)$ is even. By assumption $\widehat{\delta}(q_1, y) = q_1$.
  - $\sigma = 1 \implies$
    1. $\#_1(x)$ is odd $\implies x \in \mathcal{L}'$
    2. $\widehat{\delta}(q_1, x) := \delta(\widehat{\delta}(q_1, y), \sigma) = \delta(q_1, 1) = q_2 \implies x \in \mathcal{L}(M_2)$.
  - $\sigma = 0 \implies$
    1. $\#_1(x)$ is even $\implies x \notin \mathcal{L}'$
    2. $\widehat{\delta}(q_1, x) := \delta(\widehat{\delta}(q_1, y), \sigma) = \delta(q_1, 0) = q_1 \implies x \notin \mathcal{L}(M_2)$.
- If $\#_1(y)$ is odd...
- We proved for $x \in \{0,1\}^{j+1}$: $x \in \mathcal{L}(M_2) \iff x \in \mathcal{L}'$

The language of M_1



Theorem 11

$\mathcal{L}(M_1) = \{w10^{2k} : k \geq 0, w \in \{0,1\}^*\}$

Proof:

Claim 12 (implies the theorem)

Let $\mathcal{L}'_i = \{x \in \{0,1\}^* : \widehat{\delta}(q_1, x) = q_i\}$ and let

- $\mathcal{L}_1 = \{0^k : k \geq 0\}$
- $\mathcal{L}_2 = \{w10^{2k} : k \geq 0, w \in \{0,1\}^*\}$
- $\mathcal{L}_3 = \{w10^{2k+1} : k \geq 0, w \in \{0,1\}^*\}$

Then, $\mathcal{L}'_i = \mathcal{L}_i$ for every $i \in \{1,2,3\}$

Proving Claim ??

We need to prove that $\forall i \in \{1,2,3\}$:

$$x \in \mathcal{L}_i \iff x \in \mathcal{L}'_i.$$

Recall that

$$x \in \mathcal{L}'_i \iff \widehat{\delta}(x) = q_i$$

- Proof by induction on word length.
- Induction basis: Easy to see that hypothesis holds for ϵ.
- Induction step: Assume hypothesis holds for words of length $j \geq 0$.
- Let $x = y\sigma \in \{0,1\}^{j+1}$ for $\sigma \in \{0,1\}$.
- We prove the hypothesis for x, separately for each $i \in \{1,2,3\}$

$\mathcal{L}_1 = \{0^k : k \geq 0\}$

Recall $x = y\sigma \in \{0,1\}^{j+1}$ for $\sigma \in \{0,1\}$.

Proving: $x \in \mathcal{L}_1 \implies \widehat{\delta}(q_1, x) = q_1 \qquad (\implies x \in \mathcal{L}'_1)$.

- $x = 0^{j+1}$, $y = 0^j$ and $\sigma = 0$.
- Since $y \in \mathcal{L}_1$, by i.h. $\widehat{\delta}(q_1, y) = q_1$
- Therefore, $\widehat{\delta}(q_1, x) = \delta(\widehat{\delta}(q, y), \sigma) = \delta(q_1, 0) = q_1$. $\square$

Proving: $\widehat{\delta}(q_1, x) = q_1 \implies x \in \mathcal{L}_1$.

- Let $q_y = \widehat{\delta}(q_1, y)$ (hence, $\widehat{\delta}(q_1, x) = \delta(q_y, \sigma) = q_1$)
- $q_y = q_1$ and $\sigma = 0$. (?)
- By i.h. $y = 0^j$.
- Hence, $x = y\sigma = 0^j 0 = 0^{j+1} \in \mathcal{L}_1$. $\square$

$\mathcal{L}_2 = \{w10^{2k} : k \geq 0, w \in \{0,1\}^*\}$

Recall $x = y\sigma \in \{0,1\}^{j+1}$ for $\sigma \in \{0,1\}$.

Proving $x \in \mathcal{L}_2 \implies \widehat{\delta}(q_1, x) = q_2$.

- Assume $\sigma = 1$
  - Since $\delta(q_i, 1) = q_2$ for any $i \implies \widehat{\delta}(q_1, x) = q_2$.
- Assume $x = w10^{2k}$ for $k > 0 \quad (\implies y = w10^{2k-1}$ and $\sigma = 0)$
  - Hence, $y \in \mathcal{L}_3$.
  - By i.h. $\widehat{\delta}(q_1, y) = q_3$
  - Thus, $\widehat{\delta}(q_1, x) = \delta(q_3, 0) = q_2$.

Proving $\widehat{\delta}(q_1, x) = q_2 \implies x \in \mathcal{L}_2$.

- Assume $\sigma = 1 \implies x \in \mathcal{L}_2$. (?)
- Assume $\sigma = 0$
  - $q_y := \widehat{\delta}(q_1, y) = q_3$
  - By i.h. $y = w10^{2k+1}$ for some $k \geq 0$
  - Therefore $x = y\sigma = w10^{2k+1}0 \in \mathcal{L}_2$.

$\mathcal{L}_3 = \{w10^{2k+1} : k \geq 0, w \in \{0,1\}^*\}$

Recall $x = y\sigma \in \{0,1\}^{j+1}$ for $\sigma \in \{0,1\}$.

Proving $x \in \mathcal{L}_3 \implies \widehat{\delta}(q_1, x) = q_3$.

- $x = w10^{2k+1}$, $y = w10^{2k}$ and $\sigma = 0$
- $y \in \mathcal{L}_2$
- By i.h. $\widehat{\delta}(q_1, y) = q_2$.
- Therefore, $\widehat{\delta}(q_1, x) = \delta(q_2, 0) = q_3$. $\square$

Proving $\widehat{\delta}(q_1, x) = q_3 \implies x \in \mathcal{L}_3$.

- Let $q_y = \widehat{\delta}(q_1, y)$
- Hence, $q_y = q_2$ and $\sigma = 0$ (?)
- By i.h. $y = w10^{2k}$
- Therefore, $x = y\sigma = w10^{2k}0 \in \mathcal{L}_3$. $\square$

Part III

Regular Operations

Additional examples of regular languages

Let $\Sigma = \{0, 1\}$.

- $\{w \in \{0,1\}^* : \#_1(w) \equiv 0 \bmod 7\}$.
- Sequence of 0 followed by sequence of 1, i.e., $\{0^m 1^n : m, n \geq 0\}$.
- Any finite language.

All the above languages are regular

Is there a simple proof?

The regular operations

Let $\mathcal{A}$ and $\mathcal{B}$ be languages.

The union operation:

$$\mathcal{A} \cup \mathcal{B} = \{x : x \in \mathcal{A} \vee x \in \mathcal{B}\}$$

The concatenation operation:

$$\mathcal{A} \| \mathcal{B} = \{xy : x \in \mathcal{A} \wedge y \in \mathcal{B}\}$$

The star operation:

$$\mathcal{A}^* = \{x_1 x_2 \dots x_k : k \geq 0 \text{ and each } x_i \in \mathcal{A}\}$$

The regular operations – Examples

Let $\mathcal{A}$= {good, bad} and $\mathcal{B}$ = {boy, girl}.

Union

$$\mathcal{A} \cup \mathcal{B} = \{\text{good}, \text{bad}, \text{boy}, \text{girl}\}$$

Concatenation

$$\mathcal{A} \| \mathcal{B} = \{\text{goodboy}, \text{goodgirl}, \text{badboy}, \text{badgirl}\}$$

Star

$$\mathcal{A}^* = \{\varepsilon, \text{good}, \text{bad}, \text{goodgood}, \text{goodbad}, \text{badbad}, \text{badgood}, \ldots\}$$

Closure under union

Theorem 13

If $\mathcal{L}_1$ and $\mathcal{L}_2$ are regular languages, then so is $\mathcal{L}_1 \cup \mathcal{L}_2$.

Approach to Proof:

- Some DFA M_1 accepts $\mathcal{L}_1$
- Some DFA M_2 accepts $\mathcal{L}_2$
- Construct DFA M that accepts $\mathcal{L}_1 \cup \mathcal{L}_2$.

Attempted Proof Idea:

- first emulate M_1, and
- if M_1 doesn't accept, then emulate M_2.

What's wrong with this?
Fix: Emulate both machines simultaneously.

Closure Under Union: Correct Proof

Suppose

- $M_1 = (Q_1, \Sigma, \delta_1, q_1, F_1)$ accepts $\mathcal{L}_1$,
- $M_2 = (Q_2, \Sigma, \delta_2, q_2, F_2)$ accepts $\mathcal{L}_2$.

Define M as follows (M will accept $\mathcal{L}_1 \cup \mathcal{L}_2$):

- $Q = Q_1 \times Q_2$.
- Σ is the same.
- For each $(r_1, r_2) \in Q$ and $a \in \Sigma$, $\delta((r_1, r_2), a) = (\delta_1(r_1, a), \delta_2(r_2, a))$
- $q_0 = (q_1, q_2)$
- $F = \{(r_1, r_2) : r_1 \in F_1 \text{ or } r_2 \in F_2\}$.
- Formal proof (next slide) ♣

(hey, why not choose $F = F_1 \times F_2$?)

Correctness of the construction

Claim 14

$\mathcal{L}(M) = \mathcal{L}(M_1) \cup \mathcal{L}(M_2)$.

Follows by the next claim.

Claim 15

$\widehat{\delta}_M((q_1, q_2), x) = (\widehat{\delta}_1(q_1, x), \widehat{\delta}_2(q_2, x))$.

Proof: By induction on word length. DIY ... ♣

Proving Claim **??**:

- $x \in \mathcal{L}(M_1) \implies \widehat{\delta}_1(q_1, x) = r_1 \in F_1$. (similar if $x \in \mathcal{L}(M_2)$.)
- By Claim **??**, $\widehat{\delta}_M((q_1, q_2), x) = (r_1, \cdot) \in F \implies x \in \mathcal{L}(M)$.

- $x \in \mathcal{L}(M) \implies \widehat{\delta}_M((q_1, q_2), x) = (r_1, r_2) \in F$.
- By Claim **??**, $(r_1, r_2) = (\widehat{\delta}_1(q_1, x), \widehat{\delta}_2(q_2, x))$.
- Hence, either $r_1 \in F_1$ or $r_2 \in F_2 \implies x \in \mathcal{L}(M_1) \cup \mathcal{L}(M_2)$.

What about concatenation?

Theorem 16

If $\mathcal{L}_1$, $\mathcal{L}_2$ are regular languages, then so is $\mathcal{L}_1 \| \mathcal{L}_2$.

Example: $\mathcal{L}_1 = \{\text{good}, \text{bad}\}$ and $\mathcal{L}_2 = \{\text{boy}, \text{girl}\}$.

$$\mathcal{L}_1 \| \mathcal{L}_2 = \{\text{goodboy}, \text{goodgirl}, \text{badboy}, \text{badgirl}\}$$

This is much harder to prove.

Idea: Simulate M_1 for a while, then switch to M_2.

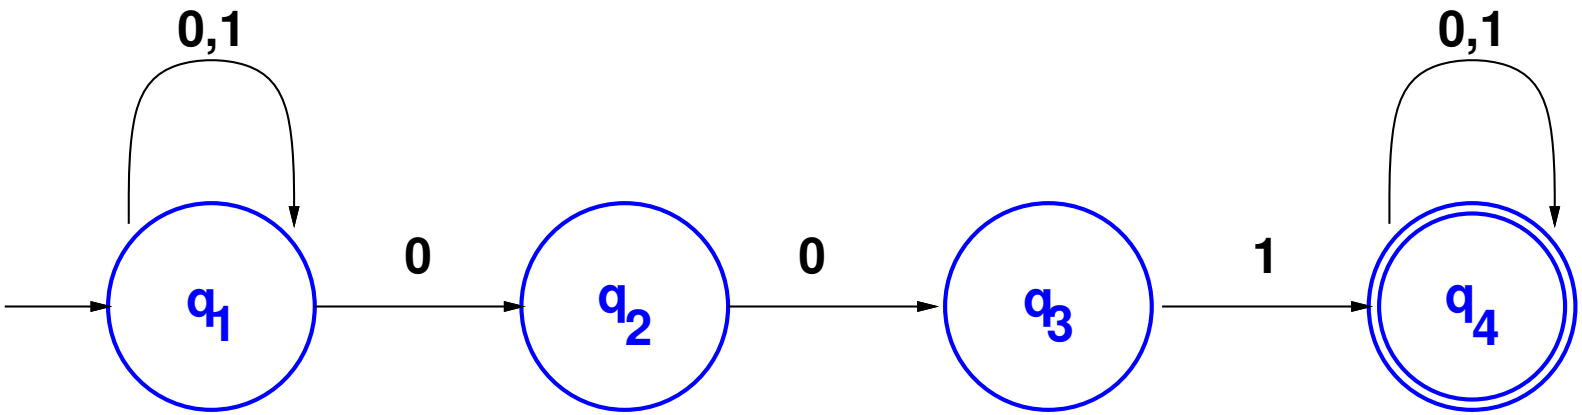
Problem: But when do you switch?

This leads us into non-determinism, wait for next class...

Part IV

Non-deterministic Finite Automata

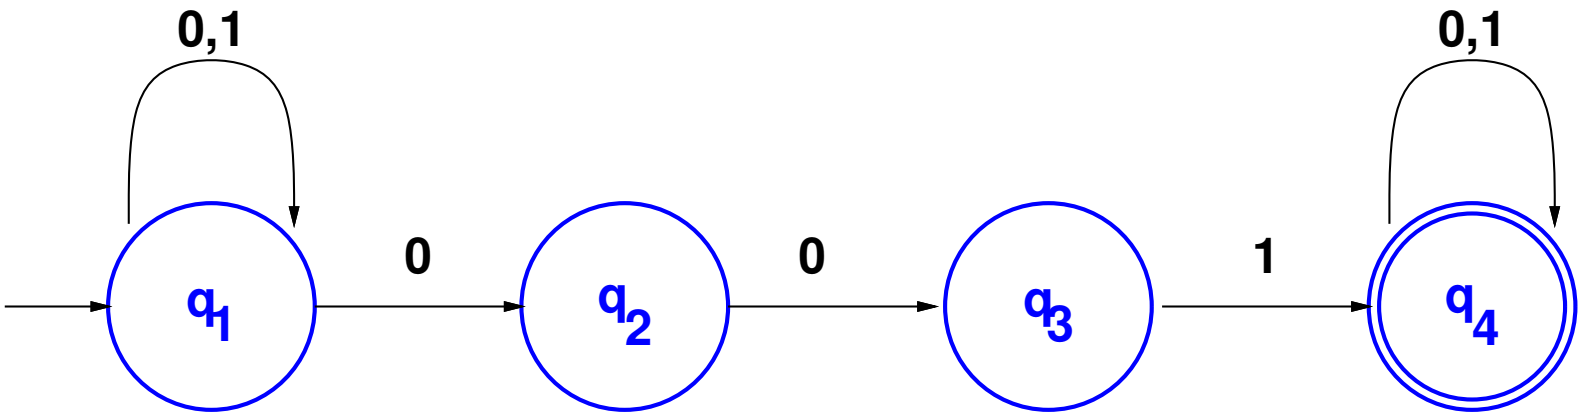
NFA — non-deterministic Finite Automata



- May have more than one transition labeled with the same symbol,
- May have no transitions labeled with a certain symbol,
- May have transitions labeled with ε, the symbol of the empty string. Will deal with this latter

Every DFA "is" also an NFA.

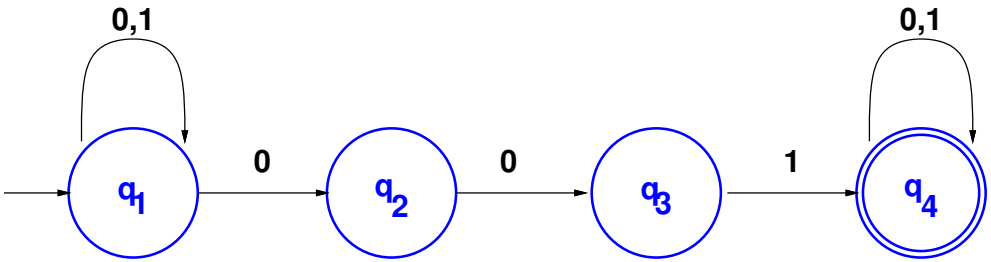
Non-deterministic computation

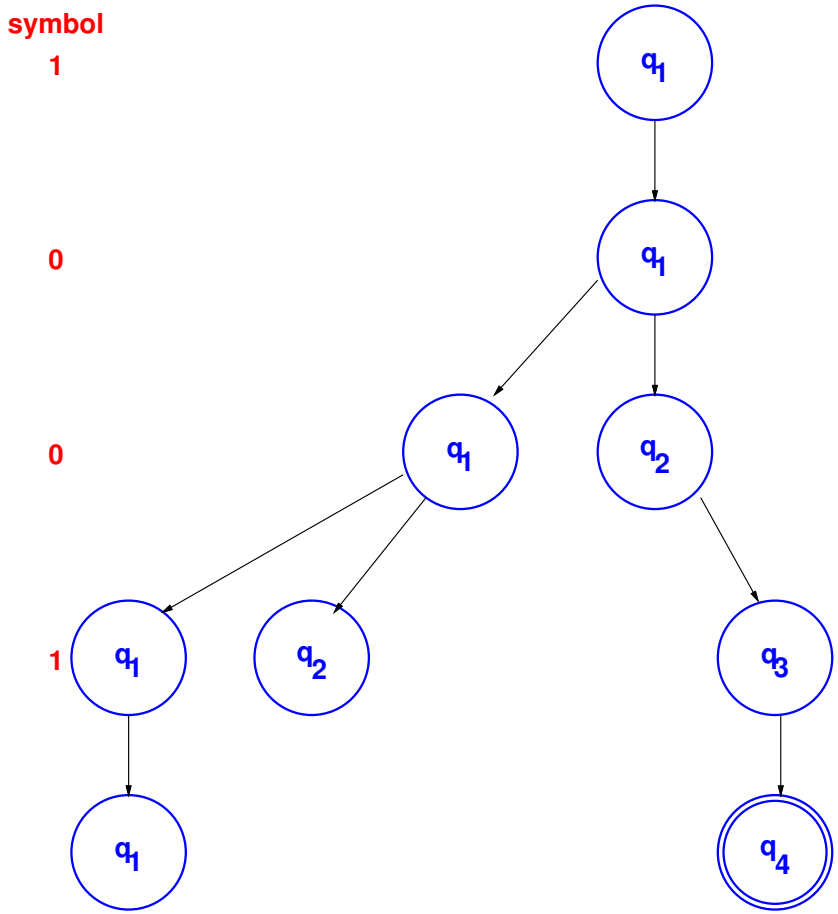


What happens when more than one transition is possible?

- The machine "splits" into multiple copies
- Each branch follows one possibility
- Together, branches follow all possibilities.
- If the input doesn't appear, that branch "dies".
- Automaton accepts if some branch accepts.

Computation on 1001





Why non-determinism?

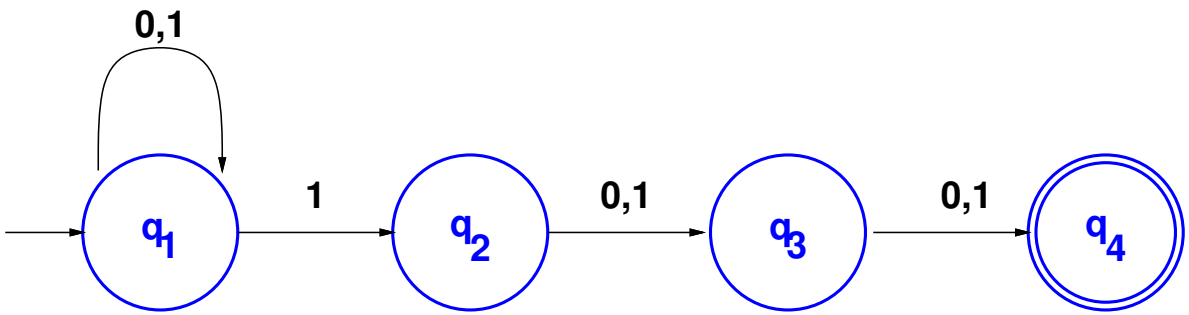
Theorem 17 (Informal, to be proved soon)

Deterministic and non-deterministic finite automata, accept exactly the same set of languages.

Q.: So why do we need NFA's?

Design a finite automaton for the language $\mathcal{L}$ — all binary strings with a 1 in their third-to-the-last position?

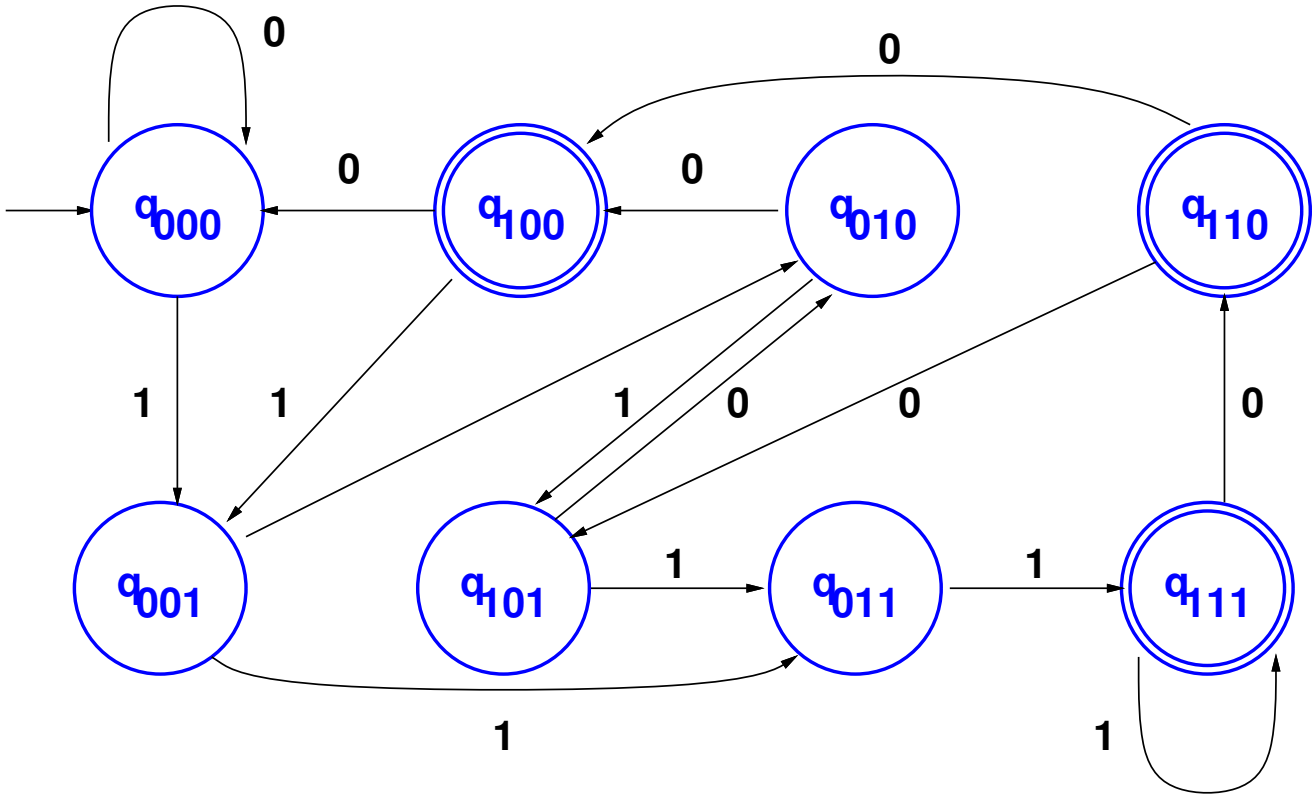
NFA for $\mathcal{L}$



- "Guesses" which symbol is third from the last, and
- checks that indeed it is a 1.
- If guess is premature, that branch "dies", and no harm occurs.

DFA for $\mathcal{L}$

- Have 8 states, encoding the last three observed letters.
- A state for each string in $\{0,1\}^3$.
- Add transitions on modifying the suffix, give the new letter.
- Mark as accepting, the strings $1**$



DFA has few bugs...
